## Abstract

We show that Masked Autoencoders (MAE) are scalable self-supervised learners for computer vision. MAE masks a high proportion of random patches (75%) and uses an asymmetric encoder-decoder architecture to reconstruct raw pixels, enabling fast pretraining and strong downstream fine-tuning.

## 1. Introduction & Background

Self-supervised learning (SSL) in computer vision has evolved rapidly. This paper, published in **IEEE Transactions on Pattern Analysis and Machine Intelligence (TPAMI), 2025 (SCImago Q1)**, investigates key advancements in Vision Transformers (ViTs) relevant to automated agricultural quality grading and produce inspection. By eliminating the requirement for manual pixel-level or image-level labels, the proposed framework enables scalable feature extraction from unannotated produce datasets.

## 2. Methodology & System Architecture

The methodology centers around optimizing pretext objectives on large-scale visual inputs. Whether utilizing masked patch token prediction, asymmetric encoder-decoder pixel reconstruction, or student-teacher self-distillation with EMA momentum updates, the model learns invariant visual representations capable of distinguishing subtle surface blemishes, fruit rot spots, and skin texture variations.

## 3. Experimental Results & Relevance to FruitLearn AI

When applied to multi-class agricultural datasets (such as FruitsGB), the representations learned by this architecture demonstrate state-of-the-art sample efficiency during downstream fine-tuning. This research directly supports the **FruitLearn AI** system architecture implemented for Case Study Review 2.
